Table S5. Analysis of variance for biomass and root-related traits in the lysimeter study

Establishment	Source	Biomass	RDW_ 0-20 cm	RDW_ 20-40 cm	RDW_ 40-60 cm	Root length>60cm
DSR	Water (W)	***	NS	NS	***	***
	Genotype (G)	**	***	***	*	NS
	W × G	NS	NS	NS	NS	NS
PTR	Water (W)	***	NS	***	***	***
	Genotype (G)	**	***	NS	NS	NS
	W × G	NS	NS	NS	NS	NS

*** Significant at $P < 0.001$; ** significant at $P < 0.01$; * significant at $P < 0.05$; NS not significant. Root length<60cm = root length under 60 cm depth below soil; RDW_0-20 cm = root dry weight at 0-20 cm depth below soil; RDW_20-40 cm = root dry weight at 20-40 cm depth below soil; RDW_40-60 cm = root dry weight at 40-60 cm depth below soil.

Table S6. Correlations between grain yield, biomass, nitrogen use efficiency based on grain yield (NUEg), and nitrogen use efficiency based on biomass (NUEb) with root architectural plasticity based on root length density (RLD) at 15-30 and 30-45 cm depths, both determined using the same approach: Approach I Plasticity Index, Approach II Slope, Approach III AMMI (distance from the origin of PC1 vs PC2), and Approach IV Factor Analytic (absolute loading values of factor 1). These relationships were different when A) all experiments were grouped, B) puddled transplanted rice (PTR) experiments only were considered, and C) direct-seeded rice (DSR) experiments only were considered. Significant relationships are highlighted.

A. All experiments

Table S8. Yield stability and root plasticity for eight genotypes with most stable grain yield based on each approach, across all experiments except for I Plasticity index which only includes PTR (puddled transplanted) trials here. For Approaches I Plasticity Index, III AMMI (distance from the origin of PC1 vs PC2) and IV Factor Analytic (absolute loading values of factor 1), grain yield stability index values close to zero indicate that the genotype shows more stable yield, while larger root plasticity index indicates more plastic root. For Approach II Slope, grain yield stability index (slope) values less than one indicate below-average yield stability, while root plasticity index (slope) greater than one indicates above-average plasticity. The eight genotypes shown are those with the greatest degree of yield stability according to each Approach. Genotypes IR 115845-B-154, IR 115845-B-388 and UPLRi7 (in bold) were selected from those eight genotypes in each approach or more than 2 approaches as showing greater stable yield and greater root plasticity, whereas genotypes IR 94226-B-364, IR 94226-B-419 and IR64 (underlined) showed higher stable yield but less plastic root growth.

Approach	Genotype	Stability/plasticity value		
		Grain yield	RLD_15-30 cm	RLD_30-45 cm
I. Plasticity index	IR 115844-B-154	-0.6256	0.6323	0.6466

Table S9. Physiological traits (normalized difference vegetation index (NDVI), leaf osmotic potential, and canopy temperature) of genotypes in field environments for both direct-seeded rice (DSR) and puddled-transplanted rice (PTR), with stress and nitrogen treatments grouped together. Genotypes selected as stable yielding and root plastic are shown in bold, and stable yielding, less root plastic genotypes are underlined.

	NDVI	Leaf Osmotic potential (MPa)	Canopy temp (°C)

Within each column, means followed by a common letter are not significantly different by the LSD test at the 5% level of significance.

Table S10. Biomass and NUE of each genotype in the lysimeter trial. Genotypes IR 115845-B-154, IR 115845-B-388 and UPLRi7 (in bold) showed greater yield stability and greater root plasticity, whereas genotypes IR 94226-B-364, IR 94226-B-419 and IR64 (underlined) showed stable yield but less plastic root growth.

Within each column, means followed by a common letter are not significantly different by the LSD test at the 5% level of significance.

Fig. S1. Soil water potential was measured at a depth of 30 cm in the stress experiments of both direct-seeded rice (DSR) and puddled transplanted rice (PTR), as well as in the well-watered DSR experiment in 2016WS.

Fig. S2. Solar radiation, maximum and minimum temperature, and rainfall across the field experiments in this study.

Fig S3. Genotypic means of grain yield, biomass, root length density (RLD) 15-30 cm, RLD 30-45 cm, nitrogen use efficiency based on grain yield (NUEg), and nitrogen use efficiency based on biomass (NUEb) as a function of the mean value in each environment. The slopes of these linear regressions were used as the stability/plasticity index for Approach II Slope.

Fig S4. AMMI grain yield stability (PC1) vs. lysimeter root plasticity index at the most shallow depth sampled (0-20 cm).

Fig S5. Linear regression between biomass and biomass stability index based on four approaches: I. Plasticity Index (A), II. Slope (B), AMMI (distance from the origin of PC1 vs PC2) (C) and Factor Analytic (absolute loading values of factor 1) (D).

Fig S6. Correlations of NUEg (grain yield/N uptake; A,C) and NUEb (biomass/N uptake; B,D) with biomass stability of each genotype based on Approach I Plasticity Index for direct seeded (A,B) and puddled transplanted (C,D) rice across environments.

Fig S7. Counterpart to the establishment methods and treatments shown in Fig 5 comparing genotypes with stable yield and more plastic root growth (IR 115845-B-154, IR 115845-B-388 and UPLRi7), genotypes with stable yield but less plastic root growth (IR 94226-B-364, IR 94226-B-419 and IR64). Under puddled transplanted rice (PTR): A) nitrogen use efficiency (NUEg), and B) leaf osmotic potential. Under direct-seeded rice (DSR): C) root length density (RLD) at 15-30 cm depth. Genotypic comparisons are shown in Tables S4 and S9.

Fig. S8. Normalized difference vegetation index (NDVI) measured in direct-seeded rice (DSR) experiments. Genotypes with stable yield and more plastic root growth (IR 115845-B-154, IR 115845-B-388 and UPLRi7) are indicated by solid lines and genotypes with stable yield but less plastic root growth (IR 94226-B-364, IR 94226-B-419 and IR64) are indicated with dashed lines. Genotypic comparisons are shown in Table S9.

Fig. S9. Average canopy temperature in each trial. Genotypic comparisons are shown in Table S9.

Fig. S10. Greenhouse lysimeter study results: A) normalized water uptake rates and B) apparent leaf area.

Fig. S11. Chlorophyll concentration index across trials in A) DSR treatments, B) PTR treatment and C) in the greenhouse lysimeter study.

Fig. S12. Water use efficiency (shoot biomass/total water uptake) in the greenhouse lysimeter study.

Fig S13. Linear regression of N uptake with shallow roots based on root length density at the 0-15 cm depth (A) in well water and drought stress treatments of two establishments in the field trials and with deeper roots based on root dry weight at 20-40 cm (B) in drought stress treatment of two establishments in the lysimeter trial.
